The valve comprises a housing having a bore in which a valve body is movably mounted. The valve body is provided with at least one passage opening for a flow which is to be controlled. The valve body has a sealing surface which faces the valve body. The sealing surface is located on a first side of the valve body and the passage opening extends through the valve body. The valve body is actuated by a valve actuator. The valve actuator has an actuating device which acts on the valve body on the second side of the valve body opposite the sealing surface and which causes the valve body to be moved into its open position. A seal is provided between the sealing surface and the actuating device which seal is intended to prevent the valve body from being actuated by the actuating device. Valves of the type referred to in the opening part of this specification are known. Such valves are used in pipelines or other conduits to control or regulate the flow of liquid or gaseous material. There are valves which control the flow of material by means of a so-called stuffing box which contains a spring-loaded packing and which is arranged to seal off a passage opening in the valve body. Such valves have the disadvantage that they produce a considerable amount of noise during the opening and closing of the valve and are relatively expensive to manufacture. Valves of the type referred to in the opening part of this specification in which a seal is provided between the sealing surface on the valve body and the actuating device are also known. In such valves it is ensured that the flow of liquid or gaseous material is controlled by the seal alone. For this purpose, the valve body is designed with a relatively small passage opening so that a seal which has a diameter considerably larger than the passage opening is provided between the valve body and the sealing surface. Such a seal consists for example of a rubber ring which is so wide that it almost completely surrounds the valve body. The valve body is usually made of metal

To do this, the material needs to be machined to size, but with an angle grinder this is not difficult. After cutting the board to shape, a crosscut table saw makes quick work of the rest. Full tutorial with photos of this project on our blog: Find that this idea is similar to another on the site, but I can't find it again! I have been going over this and it seems to be that 'rotating' the plane 90 degrees to a vertical plane (like the back of the plane) is not easy.

The reason is that there is no longer a 'normal', but a 'normal-measured-at-some-angle' I am hoping I am wrong. This is a three part tutorial that I have posted on our website, with three different techniques. The last one is the 'easy' one, but you still 81e310abbf
